

FILTER RACK

ABSTRACT

The subject matter under consideration is directed to filter racks that can be assembled and installed to hold filters and filter elements in a forced air-circulating environment such as a heating and air conditioning system. The filter rack has longitudinal members that are assembled to form a rectangular frame using readily available hardware. The longitudinal members include two side members and a back member, preferably made from the same material and having the same cross sectional profile, as well as a front member and a door. The cross-sectional profile of the side members, back member, and the front member include flanges to provide a filter rack that can receive and retain a rectangular filter when assembled.
